Introduction

In this report, our team will outline all steps we took to accomplish our final prototype. We will discuss the printing of the electronic housing, the manufacturing of the sensor housing, the final wire diagram will be produced, as well as the code used to finally run the sensors. We will also discuss any changes related to our design, we will go into detail on how the product works and what feature are included as well as which ones were removed.

Prototyping

3D Printing and Manufacturing

Our team has printed housing units for our screen, electronics, and wiring. They were 3D printed on November 21st in the Maker Space Solidworks provided by the University of Ottawa as seen in figure 1. The casing was redesigned since previous models only accounted for the exact measurement of the screen and remote, which has been a problem since without extra space both can fit the holes/holders they were meant to be in. This housing unit can hold all the important electronics such as the screen, wires, clock module, IR receiver and Arduino with all the wires that come with that as seen in figure 2.

The housing unit for our pressure sensors are made by Saxon Precision Incorporated as seen in figure 3. The length between our sensors is ~12.5 inches and is made of stainless steel. The pressure sensors will screw in on either side, with their wires being protected by making sure the unit is waterproof by using a sealant.

Changes Since Deliverable G

Since the last deliverable, we have decided to switch from Bluetooth to hardwiring our computer into the Arduino to log the data. Our team is having issues with our HC-05 Bluetooth sensor. The HC-05 Transceiver is a device which can receive and send data but during our testing, we were only able to get the device to receive data from our external device, but we could not get the HC-05 to send our data to our external device. After numerous hours of testing with this device, we concluded that we believe the pin related to transferring data is defective due to manufacturing reasons. Our data will now be logged by plugging our Arduino into our laptop and feeding the data from the serial monitor into python.

Prototype Test Plan

	system is	sensor, 1 Arduino, 1 LCD screen, 1	2.Input	as planned	
	working	IR receiver, 1 button, 1 Bluetooth	conditions		
		module, 1 real-clock module.			

Test 1: Pressures Sensor

The testing of the pressure sensors did not yield the desired results. Our value of specific gravity was found to be around 0.80, which is off by a fair margin. Our team thought of why this was, as the results in the previous tests were much better in comparison to ones we got here.

One problem could be the wires, as we unknowingly used wires with different specifications for voltage and amperes. This may cause the electricity to travel through the wires differently from one another, hence giving us an error in our signal. To solve this potential problem, removing the wires we had soldered on, and we will be soldering wires with the same type specifications to make sure this is not the issue. Another foreseeable problem is that our pressure sensors may not be accurate enough as we want. Though with our previous tests, this is the least likely. We are also seeing if the housing unit for all the wires and bread boards are not also interfering with the wires in any way in our next experiments. Overall, we hope to improve our accuracy and figure out any other problems we may have before design day on December 1st.

Figure 5: Testing All Components

Test 2: LCD and IR System

To ensure our user interface is working exactly as planned, we wired everything together except our pressure sensors and temperature sensors to simplify our values. When the system is turned on, you will see the message "Hit Start to begin" as seen in figure 5. Once the red power button is hit on the remote control, the system will begin to measure specific gravity and temperature. On the LCD display, the specific gravity is in kg/m^3 and in Plato as seen in figure 6. To view the temperature, you hit the white button to switch the display as seen in figure 7. To reset the system to the initial state, we hit the Vol + button as seen in figure 8. While the system is running, data will be shown on the serial monitor as seen in figure 9 in the format of Date, Plato, and Temperature. This data will then be streamed into a CSV file as seen in figure 10. The stream of data was only done with the date to simplify the test.

Wrike Link and Project Plan

Our project plan for the last 2 weeks is to prepare our prototype for Design Day on December 1st. We plan to do one last test on the pressure sensors November 29th for our final test. In addition to preparing for Design Day, our team will be going through all our documentation completed during deliverables A to H to put together the user manual to accompany our prototype into our MakerRepo.
